

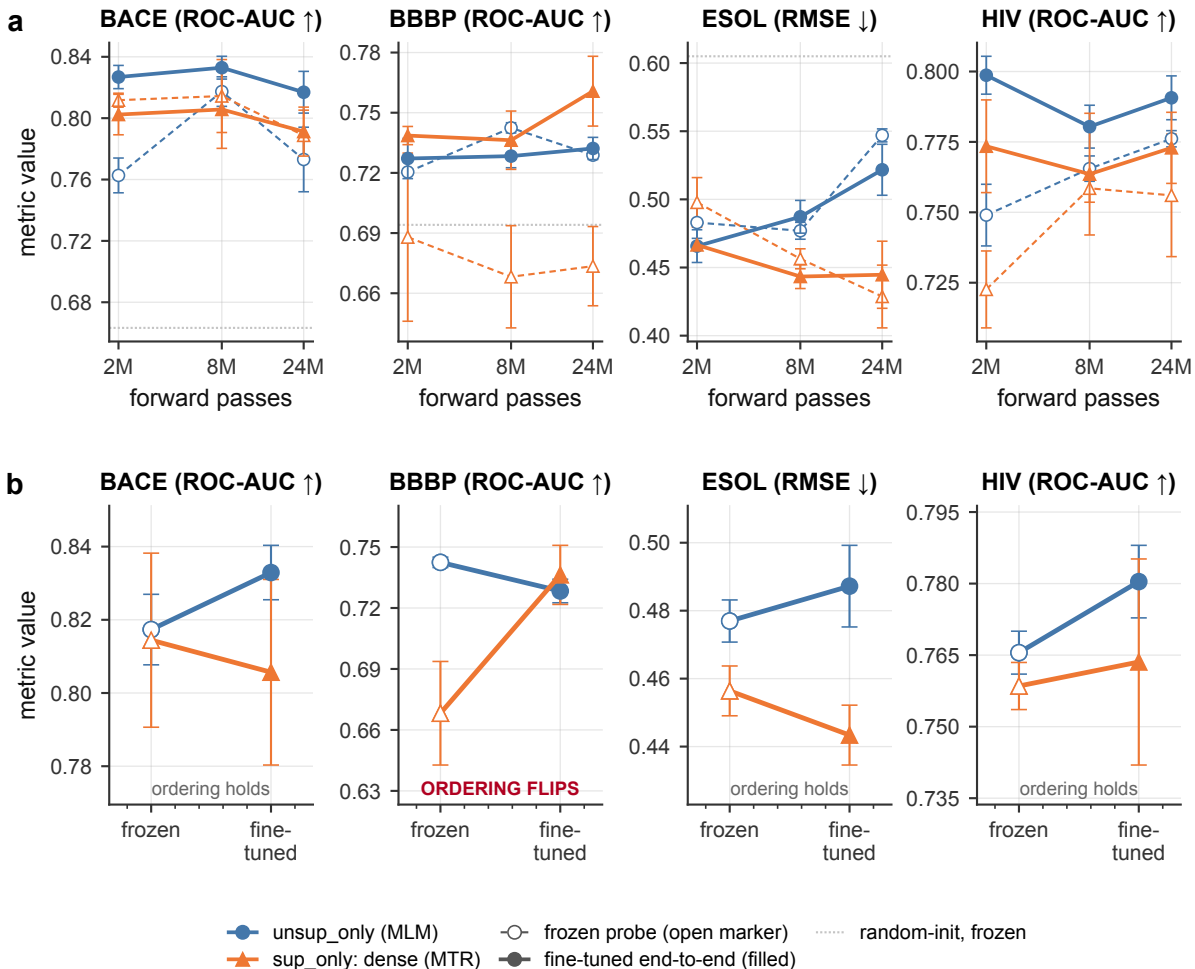

Fig E1 (H5) - is the sup_only / unsup_only ordering a frozen-probe artifact?

(b) is the matched 8M rung of (a), zoomed to its own range so a crossing is visible. Error bars: dashed/open = ± 1 sd over 3 head seeds - a frozen probe has no other randomness, the encoder is fixed; solid/filled = ± 1 sd over 3 fine-tuning seeds, which re-randomise the head AND the encoder optimisation, so the two are not the same quantity. HIV is scored by ROC-AUC here (the fine-tuning harness's metric), not the NEF1% used in A1/A2.
